Prevention of blindness

South Sudan has a huge burden of blindness with an estimated prevalence in excess of 1.5% and it is a common reason for patients attending a primary care facility [1]. Seventy five percent of this blindness can be prevented or treated by properly trained middle cadre eye health worker working with simple diagnostic tools in a primary health care setting or by referring to secondary care in a timely manner. In addition to the common causes of visual loss South Sudan suffers with the burden of two infectious diseases, Trachoma predominantly to the East of the Nile and Onchocerciasis to the West of the Nile [2]. It is therefore crucial that the following simple measures are applied at a community level to prevent eye disease and avert blindness.

1. A diet rich in vitamin A and proteins: (green leafy vegetables, yellow fruits, fish, milk, beans).
2. Personal and environmental hygiene: (regular hand and face washing, proper disposal of garbage, human and animal waste and maintenance of a clean family environment).
3. Prevention of eye injuries: (education on vehicle seat belt usage and prevention of injuries in the home and workplace).
4. Improve uptake of childhood immunization.
5. Reduction of neonatal infection: (routine application of tetracycline ointment immediately at birth).
6. Early referral and prompt treatment of serious eye diseases or injuries.
7. Avoidance of both traditional eye medicine and sharing of medication between people.
8. Improvement in management of chemical injury: (immediate flushing of eyes with clean cold water or milk).

Symptoms of eye disease

Some eye diseases, for example cataract, glaucoma and diabetic retinopathy may be present for a long time before symptoms develop, so patients present late with advanced disease. Population wide screening for these conditions would enable early detection, treatment and prevention of sight loss. All adults over the age of 40 years ideally should have a checkup by an eye care worker every two years.

Ophthalamic diagnosis is established firstly by listening to the details of the patient’s complaint, both in terms of visual symptoms and visual function, before examination and investigation. Specific symptoms as listed in Table 1 are particularly helpful in reaching a diagnosis.

Examination of eyes

Equipment required

In a primary health care setting the following simple equipment is sufficient for examination of the front half (anterior segment) of the eye where 80% of eye problems occur:

Essential equipment

- Visual acuity chart and pinhole cover.
- Torch.
- Fluorescein dye drops or strips.

Preferable equipment

- Magnifying loupe.
- Ophthalmoscope with a blue filter.
- Local anaesthetic and dilating eye drops.

STEP 1: Assessing visual acuity – see Figure 1

Diagnosis of eye disease begins with testing distance vision (visual acuity) using the modified Snellen “Tumbling E” eye chart, or picture chart. Every health worker should know how to measure and interpret visual acuity, the single most important test in eye examination.
The following steps should be followed:

1. Place the visual acuity chart on a wall with good lighting or hang it on a tree outside.
2. Sit or stand the patient at a distance of 6 meters away from the chart. (If there is no tape measure, walk 6 steps from the chart to determine where the patient should stand).
3. Ask the patient to cover the left eye with the palm of the hand, point out the letters or symbols in each line and let the patient respond by either naming the letters or showing the direction to which the characters of the symbol are pointing. Continue this process until the patient can no longer identify the letters or pictures correctly.
4. Identify the last line of letters the patient was able to read correctly (labeled with a number e.g. 6, 9, 12, 18, 24, etc.).
5. Write the visual acuity as a fraction:
   \[
   \text{Visual acuity} \frac{\text{Distance patient sits from the chart (usually 6 meters)}}{\text{The smallest line of letters patient able to read clearly}}
   
   \text{For example} 6/24
   
   \]
6. Repeat the test on the left eye by covering the right eye.
7. The test is repeated with the patient looking at the chart through a pinhole, which may show an improvement in the acuity measurement. The pinhole only allows parallel focused light through and reveals the potential visual acuity with corrective glasses or contact lenses.
8. If the patient cannot see any letters on the chart ask if they can count the number of fingers on one hand held at about a meter away. The acuity is recorded as ‘count fingers’ (1/CF as measured at 1 meter).
9. If the patient cannot count your fingers but can see shadows when you wave your hand in front of them, this is recorded as Hand Movements’ (1/HM).
10. If the patient cannot see hand movements then use a torch to shine a light in the eye and record the visual acuity as ‘Perception of Light’ (PL) or ‘No Perception of Light’ (NPL).

A good visual acuity is when the patient can read the 12 line or smaller (6/12, 6/9 or 6/6). Patients who can only see larger letters above the 12 line should be referred to an eye specialist. Patients with no perception of light (NPL), rarely benefit from medical or surgical intervention but (if both eyes are similarly affected) require a needs assessment for visual rehabilitation when available.

**STEP 2: Inspect the eye**

The eye is inspected with the help of a light and magnification when available (loupes or ophthalmoscope dialed up to +10 or +20). The eyelids should close without exposing the eyeball, the conjunctiva white or lightly pigmented and the cornea clear. The pupil should be black, round and of equal size in both eyes and constrict equally to light. From a distance of about 1 meter, with the ophthalmoscope, reflected light in the pupil (‘red reflex’) should be symmetrical. When asked to follow a finger, left and right, up and down the eyes should move together in parallel and the patient should not report double vision. Any abnormal findings should be documented and reported.
STEP 3: Exam the cornea with fluorescein

The health of the cornea is vital to preserve vision and must be carefully inspected. Fluorescein is an orange dye that stains any defect in the surface layer (epithelium) of corneal and conjunctival cells. The epithelial defect becomes easily visible as it fluoresces luminous yellow under a blue light.

To stain the cornea:
1. Apply 2 drops of local anaesthetic drops on the conjunctival sac.
2. Wait one minute, extend the neck, ask the patient to look up and pull down the lower lid to expose the lower fornix (gap between eyelid and eyeball).
3. Take a strip of fluorescein and put the impregnated tip in the fornix to dissolve the fluorescein in the tear film (or install a fluorescein drop if available in which case anaesthetic drops are not required).
4. Remove the strip and examine the cornea with the blue filter of the ophthalmoscope.

Patients complaining of pain, photophobia, tearing, itching and red eyes often have corneal abrasions or infective ulcers. An ulcer with typical branching appearance may be due to Herpes Simplex Viral Keratitis (HSK) which must not be treated with steroids but rather antivirals to avoid permanent damage to sight (see Caution below).

STEP 4: Evert the lid and examine tarsal conjunctiva

Lid eversion is an important skill for the primary eye care worker. It permits examination of the tarsal conjunctiva under the upper eye lid and aids in the diagnosis of trachoma, follicular conjunctivitis and hidden foreign bodies which cause corneal abrasions.

To evert the lid:
1. Let the patient be seated
2. Instill fluorescein into the lower lid fornix as described above
3. Extend the neck of slightly and ask the patient to look down
4. Hold the upper lid margin (usually gripping the eye lashes) between the thumb and index finger of your right hand and pull it down gently
5. Place the index finger of the left finger or cotton tipped applicator held in the left hand on the skin crease and flip the lid to expose the inner surface of the lid exposing the tarsal plate.
6. Inspect the conjunctiva and note blood vessels and presence of follicles which appear as white yellow pin head swellings on the tarsal plate. The presence of 5 or more follicles indicates presence of trachoma and lacerations or foreign bodies will fluoresce.

Some predisposed patients may develop severe acute glaucoma following dilation of the pupils, so only appropriately trained primary care workers should complete the eye examination with digital assessment of the eye pressure and ophthalmoscopic examination of the retina and optic nerve.

Management of common eye conditions see Figure 2

Eye conditions which should be referred immediately include:
- Perforating or penetrating eye injuries or retained vegetative matter
- Sudden or unexplained loss of vision
- A white pupil in a child
- A child whose eyes are not straight
- Protrusion of the eye ball
- Painful red eye unresponsive to initial treatment and vision rapidly deteriorating

Caution: Avoid use of topical steroid preparations in primary care settings. Some antibiotic eye preparations contain steroids and may be given for an infectious condition. Steroids cause raise in intraocular pressure which is difficult to treat and may lead to blindness. Steroids can worsen fungal or viral ulcers of the cornea and reduce the ability of wounds to heal. Conditions needing steroids should first be evaluated and confirmed by an Ophthalmologist.

Conjunctivitis

Conjunctivitis presents as redness over the white of the eye often associated with discharge. The vision is usually...
SHORT ITEMS

It is important to avoid rubbing the eyes as this may worsen the condition and encourage spread to other people. Promotion of regular hand and face washing of children at home and in schools by the primary eye care worker is paramount, as a dirty face in a child is the most important risk factor for transmission of trachoma.

Other risk factors include unavailability of water, dusty environment and overcrowding.

Treat with Azithromycin tablets and tetracycline eye ointment, especially in areas where Trachoma is widespread. Often the long term effect of Trachoma conjunctivitis is in-turning of the eyelashes causing corneal scarring. In-growing eyelashes can be removed but for long-term management, referral for eyelid surgery is crucial. See Figures 3 and 4.

New born conjunctivitis

New born (neonatal) conjunctivitis occurs within 28 days of birth and is usually due to gonococcal or chlamydial infection. It is a common cause of ocular disease and blindness in children.

Prevention may be achieved by good antenatal care, prevention of sexually transmitted infection in pregnant mothers and ensuring that delivery occurs in hospital under the supervision of a qualified midwife. Immediately after birth Tetracycline ointment should be applied to the baby’s eyes by the attending nurse. Established infection may be treated as in Table 4

Traumatic eye conditions

Trauma is an important cause of ocular injury and sometimes blindness in rural farming communities and in all areas due to accidents. Vegetative injury with thorns, grass and brooms predisposes to fungal infections. Community education in the prevention of injury is an important activity of the primary eye worker. Common traumatic conditions of the eye are presented in Table 5 along with suggested treatment and action.

Sight impairment is a huge burden on an individual and their family. In many cases correct management and early referral for eye problems can result in prevention of blindness. Where this is not possible, visual rehabilitation so that a person may function independently is possible with the right help. It is advisable to know where your nearest specialist eye care worker is located and how to contact them. As a primary health care worker it is imperative to develop the skills of history taking and examination of eyes, in order to communicate effectively with the specialist eye care worker who may be able give appropriate advice over the phone and improve the outcome for the patient.

Location of eye units in South Sudan

1. Juba Teaching Hospital, Unity Avenue, Box 88 Juba
2. Martha Clinic, Anglican Diocese of Yei, Yei
3. Wau Teaching Hospital Eye Department, Wau State, Wau
4. Malakal Teaching Hospital Eye Unit, Upper Nile State, Malakal
